Nokia 7250 IXR-10/IXR-6 Interconnect Routers for SR Linux
Release 21

As part of the Nokia Data Center Fabric solution, the Nokia 7250 IXR-10/IXR-6 Interconnect Routers for SR Linux are modular routers designed for multiple roles in data center fabrics, delivering massive-scale interconnectivity for webscale, service provider, enterprise data center and cloud environments.

Overview

The Nokia Data Center platforms include the Nokia 7250 IXR-10/IXR 6, the Nokia 7220 IXR-H series and the Nokia 7220 IXR-D series of interconnect routers—all of which implement the Nokia Service Router Linux (SR Linux) network operating system (NOS). This data sheet discusses the 7250 IXR-10 and 7250 IXR-6, referred to collectively as the 7250 IXR hereafter.

Data centers require massively scalable, modular, reliable platforms that are designed to support high-speed interfaces for current and future data center network build-outs. These platforms must also support a comprehensive set of features that enable flexible interconnectivity within and across data centers.

The Nokia 7250 IXR is a high-performance, high-density, modular router designed for data center spine deployments. It offers hardware support for 400GE, 100GE, 40GE, 25GE and 10GE interfaces for intra-fabric and server connectivity.

The 7250 IXR delivers a robust and comprehensive set of capabilities, including IP routing, Layer 2 Ethernet, QoS, router security, scalable telemetry and model-driven programmability. Flexible traffic management includes big buffering, per-port queuing, shaping and policing.
The Nokia 7250 IXR routers provide unmatched scalability, flexibility and operational simplicity, enabling rapid deployment and easy adaptation to evolving needs in data center and cloud environments.

The 7250 IXR-10 is a 10-slot platform supporting a system capacity up to 230.4 Tb/s. The 7250 IXR-6 is a 6-slot platform supporting a system capacity up to 115.2 Tb/s.

These platforms support a full suite of features that set the benchmark for high availability, including redundant control, fabric, fan and power configurations.

**Nokia Service Router Linux**

Nokia Service Router Linux (SR Linux) is a Linux®-based open, extensible and resilient NOS that enables scalability, flexibility and efficiency in data center and cloud environments. The Nokia 7250 IXR implements Nokia SR Linux.

SR Linux is a key component of the Nokia Data Center Fabric solution, which also includes the Nokia Fabric Services System and the Nokia Data Center platforms.

**Ground-up, model-driven architecture delivers extensibility**

In cloud-scale data center networks, the primary challenges are scalability and ease of operations. SR Linux is designed, from the ground up, with a management architecture that meets the demands of a model-driven world where visibility—and the scalability and granularity of that visibility—are paramount.

SR Linux features a completely model-driven architecture for flexible and simplified management and operations. SR Linux delivers an extensible and open infrastructure that allows applications to define and declare their own schemas, enabling the retrieval of fine-grained system state and setting of configuration.

**Modular, state-sharing architecture**

SR Linux uses an unmodified Linux kernel as the foundation on which applications share state via a publish/subscribe (pub/sub) architecture.

The Nokia pub/sub architecture is implemented using generalized Remote Procedure Call (gRPC), protocol buffers (protobufs) and the Nokia Impart Database (IDB).

The Nokia IDB is a lightweight database that is optimized to handle high volumes of messages while protecting against any one application slowing down the whole system.

**Field-proven protocol stacks**

SR Linux leverages field-proven protocol stacks from the Nokia Service Router Operating System (SR OS), which has a strong pedigree in IP routing.

Webscale, service provider and enterprise data centers are increasingly adopting leaf-spine fabric designs using enhanced IP routing with Multiprotocol-Border Gateway Protocol (MP-BGP), Ethernet VPN (EVPN) and Virtual Extensible LAN (VXLAN) protocols. By using field-proven protocol stacks, data center operators can immediately benefit from the stability, scalability and interoperability of a resilient NOS.

**Superior CLI programmability and integration of third-party applications**

Operators can leverage command line interface (CLI) plugins to completely customize the way the CLI operates, plugging in Linux commands or pulling the state/configuration from various locations, combining them with system state/configuration to allow advanced logic.

SR Linux allows third-party applications to be fully integrated into the system and given all the same benefits as Nokia applications. This includes consistent configuration via YANG, telemetry support, life cycle management and visibility of system resources.

SR Linux offers a state-of-the-art NetOps Development Kit (NDK) for data center teams to develop new applications and operational tools in the language of their choice with deep programmatic access to, and control of, the entire system.
Nokia Fabric Services System

The Nokia Fabric Services System is a declarative, intent-based automation and operations toolkit that delivers agile and scalable network operations for data center and cloud environments.

Scalable automation for all phases of data center fabric operations

Technically, automation at scale can only be delivered through intent. The Fabric Services System is designed from the ground up for intent-based automations for all phases of data center fabric operations, including Day 0 design, Day 1 deployment and Day 2+ configuration, operation, measurement and analysis of a data center fabric.

The system uses the Kubernetes framework and benefits from an established open platform instead of reinventing key platform components. All fabric services use a distributed microservices approach, allowing Nokia to deliver a true cloud-native platform for automation and operations.

Fabric Services System digital sandbox

The Fabric Services System delivers a cloud-native digital sandbox that is a true emulation of a single data center router as a containerized SR Linux (cSR Linux) instance and a fabric of multiple cSR Linux instances. The digital sandbox as an operational tool is capable of emulating a data center fabric, application workloads and external BGP speakers.

Fabric intent (as code)

The Fabric Services System is designed to represent fabric as code. All the intent and configuration state of the data center fabric is represented in a declarative way in YAML format. This lays a strong foundation for continuous integration/continuous deployment of network infrastructure, thereby fitting into the move toward infrastructure as code.

Both fabric design intent and workload intent can be validated on the Fabric Services System digital sandbox, allowing operations teams to confidently and quickly manage the risk of a change. The digital sandbox allows the operator to first try out the changes on the virtual platform, where detailed validations can be performed, and then apply the changes to the production network.

Fabric observability

Fabric observability is a combination of telemetry data and log data collected from the fabric to monitor and provide visibility into the east-west and north-south traffic. The Fabric Services System enables a cloud-native, scale-out collector architecture so that the collection capabilities are highly distributed.

Fabric operations

The Fabric Services System combines design intent with all the telemetry data collected from the fabric and presents the data in a context relevant to the operational task. These contextual views combined with the digital sandbox enable the operations team to deliver agility with confidence and removes the barriers between cross-functional teams.

Fabric integrations

The Fabric Services System enables a flexible, cloud-native approach for external integrations, resulting in faster, customized integration in customer environments. The system can be integrated with compute virtualization, storage solutions, in-house operational tools and cloud environments.

The cloud-native integration model enables data center teams to develop their integrations in a loosely coupled manner that fits into a standard Kubernetes framework.

Software features

For details about software feature support, see the Nokia Service Router Linux data sheet.

Hardware overview

The 7250 IXR hardware delivers massive scale, openness, aggregation and interconnectivity for data center and cloud environments.
Modular and high-availability platforms

The 7250 IXR-10 and IXR-6 share common control processor modules (CPMs), integrated media module (IMM) cards and power supply units (PSUs).

The 7250 IXR sets the benchmark for high availability. The 7250 IXR-10 and IXR-6 systems support a full suite of 1+1 control, 5+1 fabric, and redundant fan and power configurations.

Each chassis uses an orthogonal direct cross-connect architecture, with IMMs connecting in front and switch fabrics and fans connecting at the rear. The lack of a backplane, midplane or midplane connector system provides a compact chassis design, optimal cooling and easy capacity upgrades.

The system uses a complete Faraday Cage design to ensure EMI containment, a critical requirement for platform evolution that will support next-generation application-specific integrated circuits (ASICs).

Switch Fabric Module (SFM2)

The 7250 IXR supports a 5+1 switch fabric design for full fabric redundancy with graceful degradation. Fans and the SFM2s are separate, ensuring a complete separation of cooling from the dataplane and enabling non-service-impacting fan replacement options.

Control Processor Module (CPM2)

The CPM2 features a multi-core x86 CPU that delivers control plane scalability and performance—a key requirement for data center leaf-spine designs.

The 7250 IXR supports dual-redundant CPMs and a fully distributed control infrastructure with dedicated CPUs per line card. Compared to single monolithic control plane systems, this distributed architecture provides optimized control plane processing without any detrimental impacts to the central CPM during system maintenance, IMM commissioning and heavy data loads. The distributed architecture also improves system security.

Integrated Media Module (IMM)

IMMs are line cards providing integrated processing and physical interfaces on a single module. IMMs are hot-swappable and provide high-capacity Ethernet interfaces with full duplex (FD) per-slot performance up to 14.4 Tb/s.

Power Supply Units (PSU)

The 7250 IXR-10/IXR-6 platforms support 12 and 6 PSUs respectively, allowing for full N+M power supply redundancy (N is active, and M is the number of protecting power supplies) and full power feed redundancy. In contrast to systems with fewer power supplies, the 7250 IXR provides added room for power growth to support system enhancements with next-generation ASICs.

Two PSU variants are available: a low-voltage DC PSU (LVDC) and a combined high-voltage DC (HVDC) and AC PSU. The PSUs are fully interchangeable between the chassis variants. The HVDC PSU option enables OPEX and CAPEX savings as a result of the power-supply and infrastructure design.

About Nokia

We create the critical networks and technologies to bring together the world's intelligence, across businesses, cities, supply chains and societies.

With our commitment to innovation and technology leadership, driven by the award-winning Nokia Bell Labs, we deliver networks at the limits of science across mobile, infrastructure, cloud, and enabling technologies.

Adhering to the highest standards of integrity and security, we help build the capabilities we need for a more productive, sustainable and inclusive world.
